

CSC2001F

ASSIGNMENT 1:

EXPERIMENT DESCRIPTION:

The following assignment is about checking or comparing the efficiency of a traditional Array and a Binary Search Tree. A CVS file with a list of 9919 entries of country names, dates and vaccination numbers. The general idea was to check if a country has had vaccines done on a particular date and how many vaccinations were completed on that date. The first part of the assignment makes use of an array as a data structure and the last part of the assignment students are required to use a Binary Search Tree (BST) to store the same set of data.

The data that is stored in these data structures is read from the provided cvs file and the file is broken down into 3 separate arrays of the country name, the date and the number of vaccinations. Various functions are necessary to make use of the data provided. Both the BST app and the Array app have a slightly similar method, with a few notable differences, that prints out the results. This method takes in the country name and the date as a parameter and is used to compare the parameter to data in the data structures.

The aim of this assignment is to compare the two data structures used, which is a traditional Array and a Binary Search Tree (BST). By using these data structures students are required to create a code that will also do comparisons when searching for an item in the data structures, the calculations should show how long or how many iterations it took to search or find a country name that matches with a specified date and how many vaccinations took place in that date, for that country.

Design of application:

Class: VaccineArray

The class VaccineArray.java is a very short class used by VaccineArrayApp.java. VaccineArray stores the accessor methods to retrieve information about the entries in the csv file. It has methods like getCountry() which returns the country name. It also has a printAll() method which returns the country name along with its vaccination numbers for a specified date.

The constructor will be used in the VaccineArrayApp class and the BSTArrayApp as well to create an object or instance of the class VaccineArray. This is to be able to access each country's name and vaccination numbers. This is going to be utilized by the printResults() and printComparisons().

Class: VaccineArrayApp

The class VaccineArrayApp contains the main class and most of the methods for part 1. This class creates an object of VaccineArray to make use of the methods in the VaccineArray class.

Methods in VaccineArrayApp:

1. `printAllresults(String place, String date)` – This method is used to search for all the 'country + date' combinations that match with the supplied data (arguments) in the traditional array that they are stored in. The data received is then captured in a text file. The textfile format is the country name and the vaccination numbers.
2. `printComparisons(String place, String date)` - This method is used to determine the number of iterations that are needed to find a specified combination of country + date. This is a way to determine the efficiency of the traditional array, by determining how many iterations are required for a data entry, the larger the overall iterations are, they less efficient the data structure being used is.

3. `calculatesubsets(int subset, String sDate, PrintWriter sampledata)` – This method is used to test the array using 10 different subsets of the original sample size that are spaced equally apart. For each of the 10 subsets, the number of iterations that are needed to find the county + date combination is determined. Using these iterations, the best case, worst case and the average case is determined for each of the 10 subsets of values and it is written to a textfile each time. The method takes in the subset, the date, and the file name to be written to as arguments.

4. `createFiles(String date)` – This method is used to create 10 different text files named sample1.txt to sample10.txt to store the results for the 10 different subsets. The method then calls the `calculatesubsets` method to write the results to the 10 different text files for the 10 different subsets

There is only one argument, it is the date.

Class: VaccineBSTApp

The `VaccineBSTApp` class is used for part three, four and five of the assignment. Information about students is now stored in a different data structure which is a BST (Binary Search Tree). This class also makes use of multiple other classes and creates objects of those classes, which are The `BinarySearchTree` class, `BinaryTree` class and `BinaryTreeNode` class.

Methods in class VaccineBSTApp:

1. `printAllresults(String place, String date)` – This method is the same as the one used in `VaccineArrayApp` except for the fact that it is used to accommodate the Binary Search Tree instead of the Array.

2. `printComparisons()` -

3. `calculatesubsets()` -

4. `createFiles()` -

Array test values and Outputs:

This is a sample from the textfile sample6.txt from Arraytextfile folder

There are 9342 iterations for Norway
There are 195 iterations for Mongolia
There are 899 iterations for Senegal
There are 4453 iterations for Madagascar
There are 2286 iterations for Trinidad and Tobago
There are 8972 iterations for Hungary
There are 1463 iterations for Curacao
There are 7444 iterations for Guatemala
There are 987 iterations for Syria
There are 9904 iterations for Cyprus
There are 5356 iterations for Chile
There are 5774 iterations for Tunisia
There are 2286 iterations for Trinidad and Tobago
There are 8818 iterations for Turks and Caicos Islands
There are 1063 iterations for Netherlands

The average case is 5071 |The worst case is 9918 |And the best case is 3

BST test values and Outputs:

This is a sample from textfile sample9.txt

There are 7 iterations for Croatia
There are 10 iterations for Cyprus
There are 16 iterations for Israel
There are 17 iterations for Kuwait
There are 10 iterations for Barbados
There are 6 iterations for Fiji
There are 13 iterations for Moldova
There are 13 iterations for Asia
There are 4 iterations for Peru
There are 7 iterations for Yemen
There are 7 iterations for Egypt

There are 8 iterations for Ukraine
There are 9 iterations for Zimbabwe
There are 10 iterations for France
There are 18 iterations for Kazakhstan
There are 14 iterations for Maldives

The average case is 6 |The worst case is 55 |And the best case is 1

Results:

This is data that is extracted from different sample files but showcasing the same countries

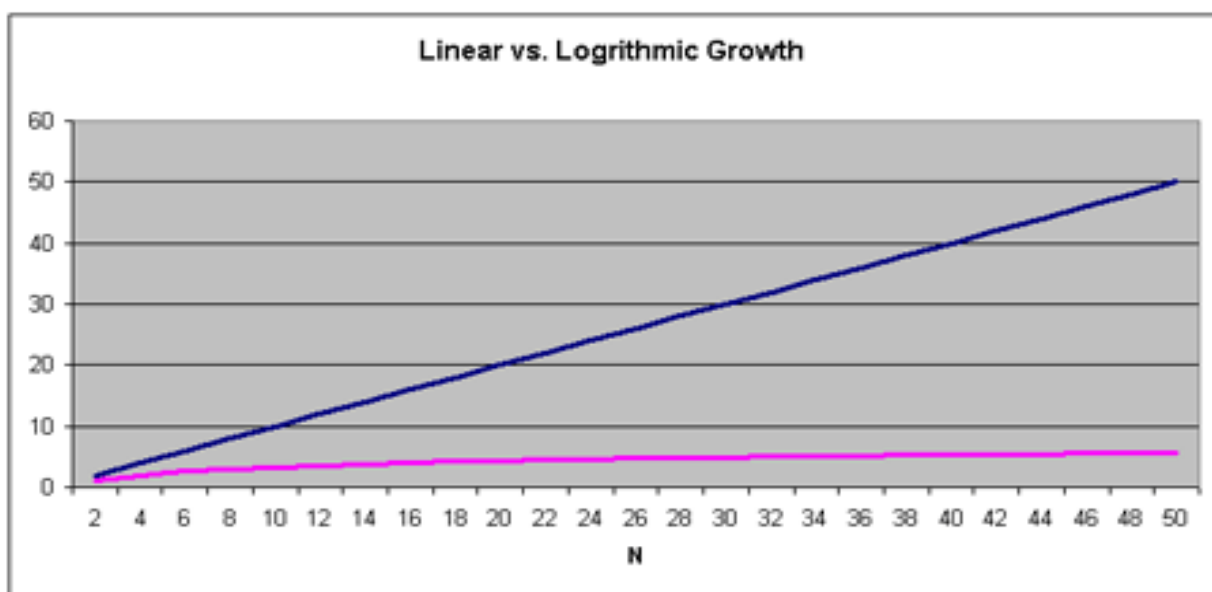

Country	Array iterations	BST iterations
Cyprus	9904	19
France	7568	10
England	4497	5

Zimbabwe	6572	9
Netherlands	1063	18
Senegal	899	6
Chile	5356	3
Maldives	9918	14
Croatia	5378	7
Canada	126	5
United States	400	21

Discussion of results:

As we can see from the above results of iterations, the BST iterations are much lower in all the iterations chosen and they seem to take a logarithmic shape. The array has to loop through every item every time it is looking for a value in the dataset, this makes the iterations for each data set to be very large and the array is linear. The formula to define the graph to draw the iterations of the Array comparisons would be $f(x) = mx + c$ and that of the BST would be $f(x) = \log(x)$. The above results also tell us that it takes less time to search through the BST data structure than an array data structure. For the first values of x when we plot them in our formula. We would get approximately the same values. But when the x value increases the linear function grows a lot compared to the log function. Hence the time it will take to do comparisons in the Array will be bigger compared to time it will take when using a binary search system.

Examples of how the graphs would look like:

Git Usage:

```
The VaccineBSTApp is working functionally and the VaccineArrayApp has also been modified with new methods being added
commit 81ca9b77571a854023c868726703ae97793d631b
Author: Nkosinathi <tshaphilenkosinathi@gmail.com>
Date:   Wed Mar 9 14:48:12 2022 +0200

    Modified the Makefile

commit 3b496bbdc2d89c9be9fc025f42ac027d06ee8826
Author: Nkosinathi <tshaphilenkosinathi@gmail.com>

:...skipping...
commit 32608eb5a9d0b68e03ef8e56fd3b51194d636bab (HEAD -> master)
Author: Nkosinathi Tshaphile <tshnko012@sl-dual-241.cs.uct.ac.za>
Date:   Fri Mar 11 23:18:06 2022 +0200

    Everything is done, this is the last commit

commit 5b9c006098479681ffe769f02e3865e37ab877ca
Author: Nkosinathi <tshaphilenkosinathi@gmail.com>
Date:   Fri Mar 11 05:30:36 2022 +0200

    The VaccineBSTApp is working functionally and the VaccineArrayApp has also been modified with new methods being added

commit 81ca9b77571a854023c868726703ae97793d631b
Author: Nkosinathi <tshaphilenkosinathi@gmail.com>
Date:   Wed Mar 9 14:48:12 2022 +0200

    Modified the Makefile

commit 3b496bbdc2d89c9be9fc025f42ac027d06ee8826
Author: Nkosinathi <tshaphilenkosinathi@gmail.com>
Date:   Wed Mar 9 14:46:31 2022 +0200

    Introduced the VaccineBSTApp application, also created a VaccineArray, all applicatins are now running successfully
```

Conclusion:

The conclusion is therefore that a BST is way more efficient to use when you have a lot of data compared to an Array. It takes less time to use a BST data Structure because it is $O(\log n)$ and linear is $O(n)$. And as the dataset size increases, so does the inefficiency of the Array data structure
